

Genetic Genealogy  
Analysis of Y-DNA Simple Tandem Repeats (STRs)  
For The DuBose-DuBois DNA Project  
by Steven James Coker  
SJCoker1@gmail.com  
28 April 2017

## A. Introduction.

Genetic genealogy provides information that helps guide and validate research conducted by genealogists. This paper will examine clade grouping for The DuBose-DuBois DNA Project based on Y-DNA Simple Tandem Repeat (STR) data. STRs are also referred to as Short Tandem Repeats.

Isaac DuBose was born about 1665 in St Jacques Parish, Dieppe, Normandy, France. Isaac died in French Santee, Charleston County, South Carolina, before 1721. Isaac DuBose married Suzanne Couillandeu about 1691 in South Carolina. The couple were French Huguenots and they are paternal 6<sup>th</sup> Great Grandparents of the writer. Suzanne Couillandeu was born in La Tremblade Provenec, Saintoge, Or, France, about 1670. Suzanne reached 72 years of age and died in Santee, Charleston, South Carolina, on June 12, 1742. She was the daughter of Pierre Couillandeu Sr and Marie Fougernaut.

In 1685, King Louis XIV revoked the Edict of Nantes which had been published in 1598 to halt the French Wars of Religion (1562-98) between Catholics and Protestants. The Edict granted religious liberty in France to the Huguenots and other French Protestants. The revocation in 1685 caused a flood of emigrants leaving France to avoid religious persecution. Isaac and Suzanne were among the many French Huguenots who came to South Carolina at that time.

Family of Suzanne and Isaac DuBose

I. Isaac DuBose 2nd was born in St James Parish, South Carolina, about 1693.

II. Elizabeth DuBose was born in Jamestown, Berkeley, South Carolina, about 1695. She died in Christ Parish, Charleston, South Carolina, in 1736 at the age of 41. Elizabeth was buried in Awendaw, Charleston County, South Carolina.

III. Daniel DuBose was born in Jamestown, Berkeley, South Carolina, about 1695. He died in St James, Clarendon, South Carolina, about June 1755 at the age of 60.

IV. John DuBose was born in Jamestown, Berkeley, South Carolina, in 1697. He died at Lynches Creek, South Carolina, in 1778 at the age of 81.

V. Mary DuBose was born in South Carolina, about 1700.

VI. Stephen DuBose Sr was born in Jamestown, Berkeley, South Carolina, on May 13, 1702. He died in South Carolina. He is the writer's 5<sup>th</sup> Great Grandfather.

VII. Peter DuBose 1st was born in Jamestown, Berkeley County, South Carolina, in 1703. He died in Christ Church Parish, Berkeley County, South Carolina, on June 9, 1755, at the age of 52.

VIII. Anthoine DuBose was born in Jamestown, Berkeley, South Carolina, about 1708.

IX. David DuBose was born in Jamestown, Berkeley County, South Carolina, in 1710. He died at Lynches Creek, Darlington County, South Carolina.

X. Andrew DuBose Sr was born in Jamestown, Berkeley, South Carolina, about 1711. He died at Lynches Creek, Darlington County, South Carolina, about 1787 at the age of 76.

XI. Amos DuBose.

The descendants of Suzanne and Isaac DuBose increased and became early and prominent settlers of South Carolina and throughout much of the United States. This paper will not attempt to name their many descendants or discuss their history. Rather it will attempt to describe the DNA of a few of the male descendants.

1731 Map of Carolina

## B. Statement of Hypothesis.

The hypothesis which will be examined is that the STR data compiled in the DuBose-DuBois DNA Project can be taken as evidence of the Y-DNA clade representing male descendants of Isaac DuBose.

## C. Methods.

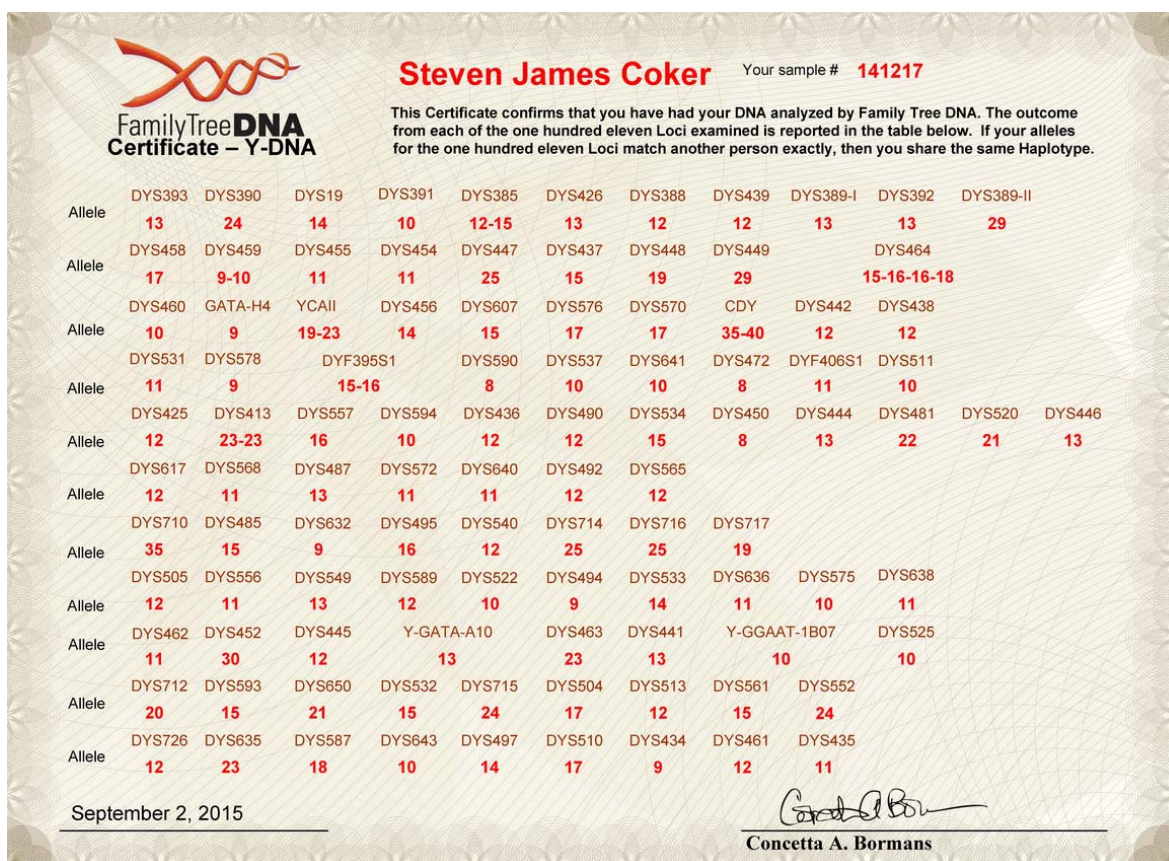

1. DNA collection. The DuBose-DuBois DNA project was started in 2004 and has grown slowly as more interested descendants have joined. The project currently has 82 members who have submitted Y-DNA samples. Of those, 29 have been identified as descendants of Isaac DuBose. The remainder include descendants from other lineages. As well as men who descended from a DuBose female and thus did not inherit the DuBose Y-DNA. The DNA project includes data on STRs and Single Nucleotide Polymorphisms (SNPs) for Y-DNA. The project also includes mtDNA and autosomal DNA data. This analysis will be limited to the Y-DNA data.

2. Data Testing. The DNA samples for this project have been collected and tested by the Family Tree DNA (FTDNA) company in Houston, Texas. All samples and data are managed, stored, and reported by FTDNA. The data is available for public viewing at the following web site.

<https://www.familytreedna.com/groups/du-bose-du-bois/dna-results>

However, some data may be restricted from view by the DNA owner. FTDNA does not take ownership of the data from individual samples. The person who submits the sample controls viewing access for data from their sample. All data is accessible to the project administrator. The writer is administrator for the project.

**FamilyTreeDNA Certificate – Y-DNA**

**Steven James Coker** Your sample # **141217**

This Certificate confirms that you have had your DNA analyzed by Family Tree DNA. The outcome from each of the one hundred eleven Loci examined is reported in the table below. If your alleles for the one hundred eleven Loci match another person exactly, then you share the same Haplotype.

Allele	DYS393	DYS390	DYS19	DYS391	DYS385	DYS426	DYS388	DYS439	DYS389-I	DYS392	DYS389-II

Example of Individual Report of STR Data.

3. Data. For this paper, I used Y-DNA STR data. I further restricted the data set to only samples that had tested 111 markers. Lastly, I used only samples in the R Haplogroup. The result of these filters left 43 subjects with data samples for study.

5. Phylogenetic Methodology. The Y-DNA STR data was compiled into an Excel spreadsheet from which a FASTA data file was created. The FASTA data was imported into MEGA. The data was aligned in MEGA using MUSCLE with Neighbor Joining clustering method. Phylogenetic analysis was done in MEGA of the aligned data using both the Neighbor-Joining and the Maximum Likelihood methods. Similar results were obtained from both methods.

6. For estimating the Time to Most Recent Common Ancestor (TMRCA) of the descendants of Isaac DuBose, I used the program by McGee at <http://www.mymcgee.com/tools/yutility111.html>

## D. Discussion and Procedures.

### 1. Converting STR Counts to ATCG.

The STR results are reported by FTDNA as repetition counts. For this analysis, I wanted to convert the counts into ATCG nucleotide sequences for which the counts are a user-friendly shorthand. This turned out to be much harder than I anticipated. I spent a considerable portion of the hours devoted to this report in attempting to discover reliable information which could be used to translate the counts into ATCG sequences. I achieved partial success in this effort. Enough to complete the analysis.

FTDNA does not publish or provide information for converting the counts into ATCG format. After considerable searching, the best conversions I found were given in the NIST table shown below. The repeat motifs in the table were sufficient for many of the STRs. But, 36 of the 111 STRs were not included in the data table. This most likely is because the table was published in 2008 and has not been updated. The repeat motifs for six of the STRs in the table were not usable because I could not find explanation of the code used in the table.

There were 112 STR data marker values available in the data set. Including multi-value markers. I found usable ATCG conversions for 70 markers. Thus, the analysis was limited to 70 STR markers.

## 2. Pruning Data.

There were a total of 82 Y-DNA STR data samples in the project. Of these, 14 had only tested to the 37 marker level, 22 had tested to 67 markers, and 45 had tested fully to 111 markers. After repeated tries, I found that including 111 markers with 37 or 67 markers in MEGA gave some illogical results in the phylogenetic analysis. Therefore, I eliminated the 37 and 67 marker samples and worked only with the 45 remaining 111 marker samples.

Two of the 111 marker samples were not in the Y-DNA R Haplogroup. I attempted running the MEGA phylogenetic analysis with both R and the two non-R haplogroup types included. But, I found that inclusion of the non-R data invariably resulted in trees that had logical flaws. One possible factor is that these two non-R samples had null data for one marker. It is apparent from the SNP data that all the known descendants of Isaac DuBose are in the R Haplogroup. Thus, I eliminated the data samples that were of non-R haplogroup.

## 3. Aligning the Data in MEGA.

I ran many simulations in MEGA. I found that the most logical phylogenetic result was obtained when the data was aligned using MUSCLE with Neighbor Joining as the clustering method.

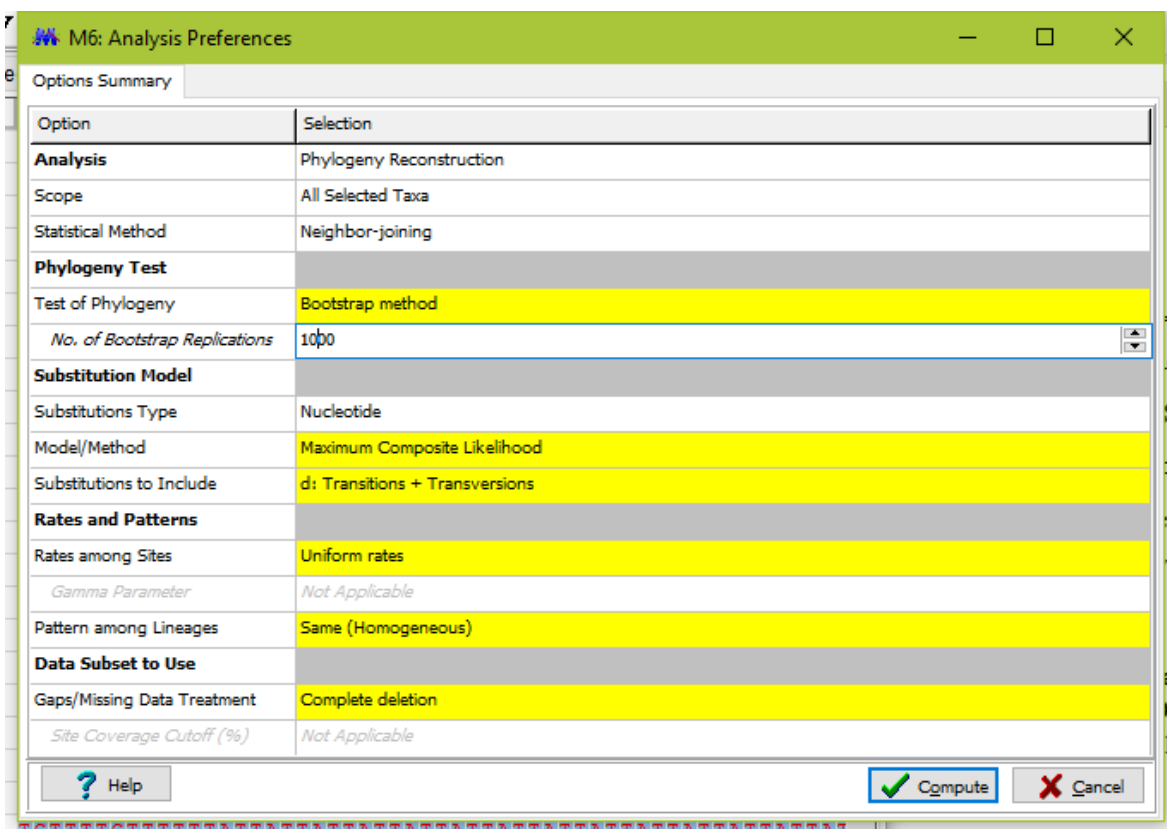

Alignment Procedure

## E. Results

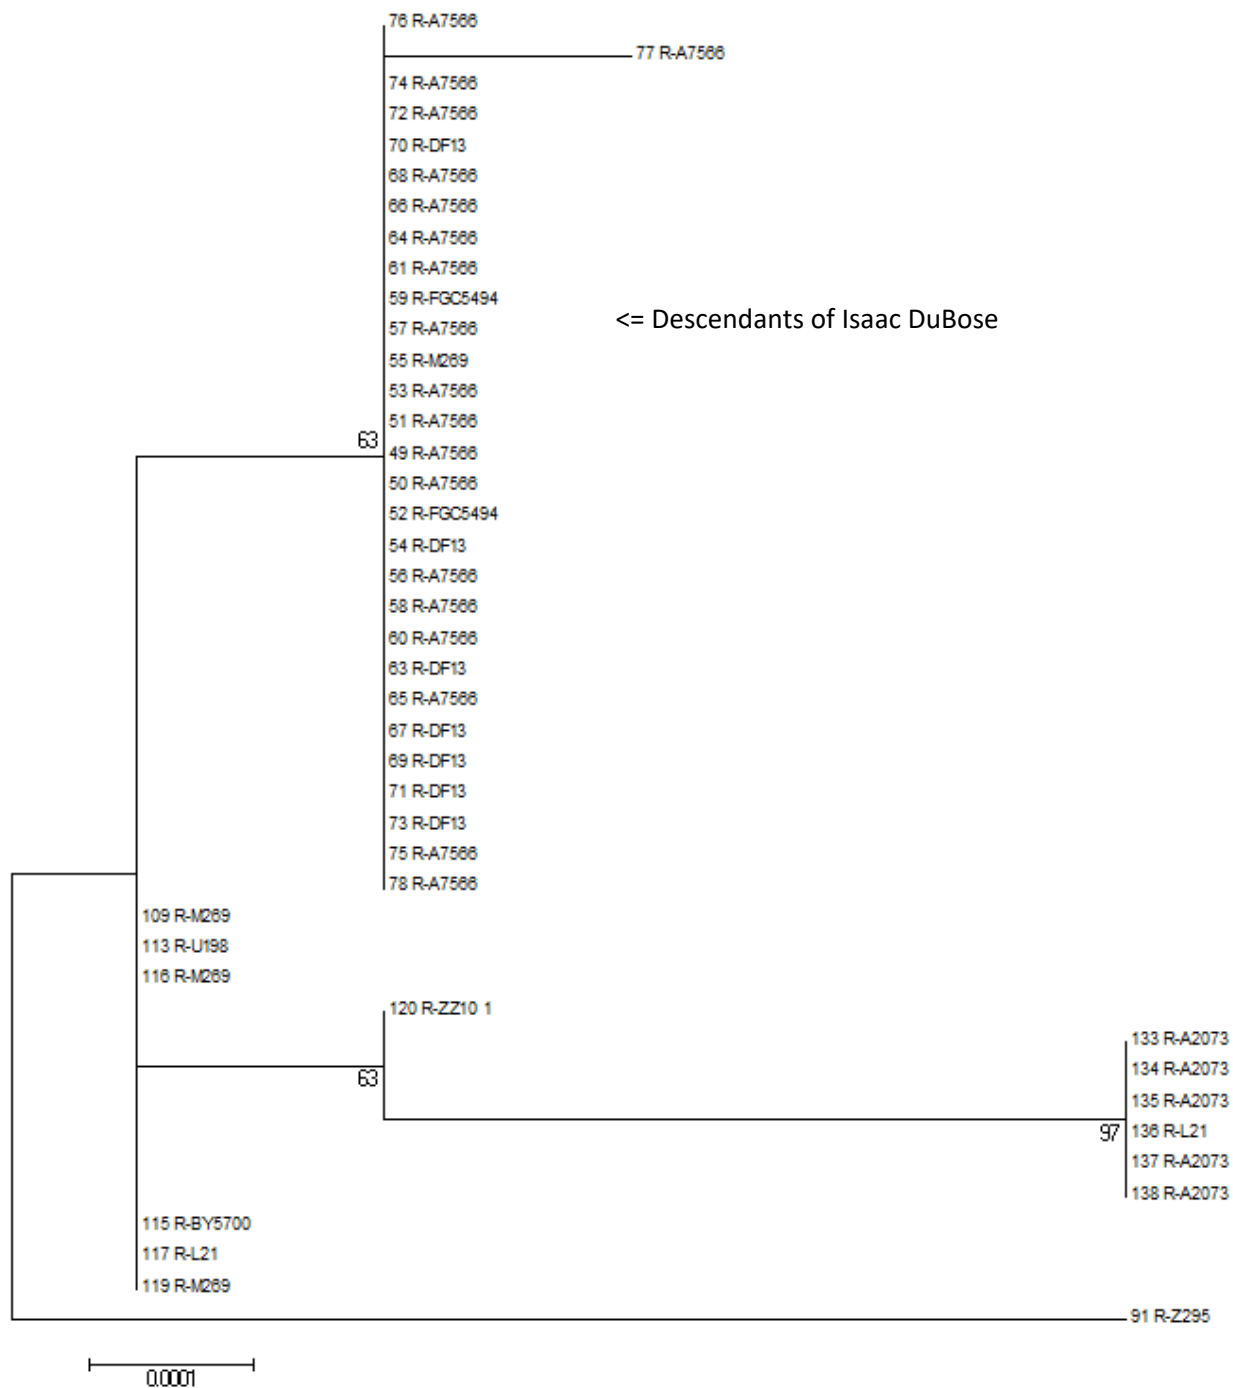

### 1. Phylogenetic Analysis in MEGA.

I tried various phylogenetic methods in MEGA. The results obtained using either Neighbor Joining or Maximum Likelihood methods appeared equivalent. In the trees shown below, the data samples are numbered with the Haplogroup and Terminal SNP shown after the sample number.

The Y-DNA clade representing descendants of Isaac DuBose are samples 49-78. Sample 62 was omitted from the analysis because it was only tested to 37 marker level.

Phylogenetic Analysis by Neighbor-Joining

0-9 Generations					10-19 Generations					20-29 Generations					30-39 Generations					Close ancestor excluded					12 Gen = Mean of Mins 10 Gen = Mode of Mins						

The above table gives the 95% probability that the MRCA was no longer than the specified generations. The algorithm was taken from Bruce Walsh paper, [Estimating the Time to the Most Recent Common Ancestor for the Y chromosome or Mitochondrial DNA for a Pair of Individuals.](#)

Values on the diagonal indicate number of markers tested. Generations assume 30 years on average per generation. Calculations use the average mutation rate for all the markers common between the pair of haplotypes being compared. Assumed mutation rates are shown in the following table.

The TMRCA analysis shows most samples share a common male ancestor within 10 to 11 generations. The adjusted average minimum generations to the common male ancestor is 12. The most common (mode) of the minimums is 10 generations. This result agrees with the approximately 350 years that have passed since Isaac was born and 325 years since Isaac and Suzanne began their family.

It is not unexpected that some samples have a larger TMRCA value and some smaller. This may be caused by variability of mutations and differences in length of average generations between lineages. Also, the assumed mutation rates are based on population studies and actual mutation rates for this group may be somewhat different.

Mutation rates not yet identified have a light green background and use the value of 0.0024 from the constant rate box														

Mutation rates not yet identified have a light green background and use the value of 0.0024 from the constant rate box

### Custom Mutation Rates Used

The default mutation rate is 0.0024 mutations/allele/generation which represents the 60 total mutations during 24870 total allele meioses as given in [Y-Chromosomal Microsatellite Mutation Rates: Differences in Mutation Rate Between and Within Loci](#) by B.Myhre Dupuy, M.Stenerson, T.Egeland, and B.Olaisen; Human Mutation 23:117-124 (2004).

The second mutation rate selection uses the FTDNA derived mutation rates. This includes a rate of 0.00399 for the first 12 markers, 0.00481 for markers 13 through 25, and 0.00748 for the markers 26 through 37.

The third mutation rate selection uses the values determined by Doug McDonald as derived from the Sorenson database. Markers not included in the Sorenson database are derived by Doug through other means. Values not included in the McDonald rates use the value in the default of 0.0024.

The Custom Values, use the McDonald Rates.

## F. Conclusions.

Based on the analysis discussed above, I conclude that The DuBose-DuBois DNA Project has correctly identified the clade of men who are descended from Isaac DuBose.

1. Genealogical research showing the ancestry of certain individuals in the project demonstrates they descend from Isaac DuBose.
2. The Y-DNA SNP haplogroup signature of men identified as descendants of Isaac DuBose is

R1b > L21 > DF13 > FGC5494 > Z16502 > A7566

See <https://www.familytreedna.com/groups/du-bose-du-bois/dna-results>

3. As presented, the phylogenetic analysis of STR data demonstrates common ancestry for the identified clade of descendants of Isaac DuBose.
4. The TMRCA analysis demonstrates that members of the identified clade share a common ancestor within the approximate expected number of generations.
